Abstract

Prolyl 4-hydroxylase (P4H) catalyzes the post-translational hydroxylation of (2*S*)-proline (Pro) residues in procollagen strands. The resulting (2*S*,4*R*)-4-hydroxyproline (Hyp) residues are essential for the folding, secretion, and stability of the collagen triple helix. Even though its product (Hyp) differs from its substrate (Pro) by only a single oxygen atom, no product inhibition has been observed for P4H. Here, we examine the basis for the binding and turnover of substrates by human P4H. Synthetic peptides containing (2*S*,4*R*)-4-fluoroproline (Flp), (2*S*,4*S*)-4-fluoroproline (flp), (2*S*)-4-ketoproline (Kep), (2*S*)-4-thiaproline (Thp), and 3,5-methanoproline (Mtp) were evaluated as substrates for P4H. Peptides containing Pro, flp, and Thp were found to be excellent substrates for P4H, forming Hyp, Kep, and (2*S*,4*R*)-thiaoxoproline, respectively. Thus, P4H is tolerant to some substitutions on C-4 of the the pyrrolidine ring. In contrast, peptides containing Flp, Kep, or Mtp did not even bind to the active site of P4H. Each proline analog that does bind to P4H is also a substrate, indicating that discrimination occurs at the level of binding rather than turnover. As the iron(IV)-oxo species that forms in the active site of P4H is highly reactive, P4H has an imperative for forming a snug complex with its substrate, and appears to do so. Most notably, those proline analogs with a greater preference for a C$^\gamma$-*endo* pucker and *cis* peptide bond were the ones recognized by P4H. As Hyp has a strong preference for C$^\gamma$-*exo* pucker and *trans* peptide bond, P4H appears to discriminate against the conformation of proline residues in a manner that diminishes product inhibition during collagen biosynthesis.

Collagens are the major structural proteins in the extracellular matrix. All collagens are comprised of three polypeptide strands that coil together into a right-handed triple helix. Each strand contains a repeating three amino-acid sequence in which every third residue is a glycine (Gly[1]): Xaa–Yaa–Gly. The Xaa position is often (2*S*)-proline (Pro), and the Yaa position is often (2*S*,4*R*)-4-hydroxyproline (Hyp) (1). Hyp is produced by the action of prolyl 4-hydroxylase (P4H; EC 1.14.11.2). This post-translational modification is the most prevalent

[1]Abbreviations: Boc, *tert*-butyloxycarbonyl; DMF, dimethylformamide; ESI–MS, electrospray ionization mass spectrometry; Flp, (2*S*,4*R*)-4-fluoroproline; flp, (2*S*,4*S*)-4-fluoroproline; Fmoc, fluorenylmethoxycarbonyl; FPLC, fast protein liquid chromatography; Gly, glycine; HPLC, high-performance liquid chromatography; Hyp, (2*S*,4*R*)-4-hydroxyproline; hyp, (2*S*,4*S*)-4-hydroxyproline; Kep, (2*S*)-4-ketoproline; MALDI–TOF, matrix-assisted laser desorption/ionization time-of-flight; MCPBA, 3-chloroperoxybenzoic acid; Mtp, 3,5-methanoproline or 2-azabicyclo[2.1.1]hexane-3-carboxylic acid; PEG, poly(ethylene glycol); P4H, prolyl 4-hydroxylase; Pro, (2*S*)-proline; TEMPO, 2,2,6,6-tetramethylpiperidine-1-oxyl; TFA, trifluoroacetic acid; Thp, (2*S*)-4-thiaproline; Thp(O), (2*S*,4*R*)-4-thiaoxoproline; thp(O), (2*S*,4*S*)-4-thiaoxoproline; Thp(O,O), (2*S*)-4-thiadioxoproline.

in the kingdom Animalia, where Hyp is more common than seven of the "common" amino-acid residues: Cys, Gln, His, Met, Phe, Trp, and Tyr.[2] The presence of Hyp is crucial for the folding, secretion, and stability of the collagen triple helix under physiological conditions (4–7), and P4H activity is necessary for the viability of the nematode *Caenorhabditis elegans* (8–10) and the mouse *Mus musculus* (11). The enzyme-catalyzed hydroxylation of proline residues also plays a role in the sensing of molecular oxygen, though those enzymes are distinct from the P4H that acts on collagen (12).

P4H is a tetrameric enzyme comprised of two α subunits and two β subunits. Each α subunit (59 kDa) contains a catalytic domain and a peptide-binding domain (13). The β subunit (55 kDa) is protein disulfide isomerase (14), which is necessary to keep the α subunit from aggregating (15,16) and to retain the enzyme in the endoplasmic reticulum (17). The study of P4H has been facilitated by the recent development of recombinant DNA systems for the high-level production of active P4H tetramers in *Escherichia coli* (18,19). Still, the three-dimensional structure of P4H remains unknown.

P4H is a non-heme iron(II) dioxygenase (20–22). This class of enzymes uses α-ketoglutarate and O_2 as co-substrates (Figure 1). Hydroxylation of proline is accompanied by the oxidative decarboxylation of α-ketoglutarate to form succinate (23). During the reaction, one atom of molecular oxygen is incorporated into Hyp, and the other into succinate (24). Uncoupling of the decarboxylation of α-ketoglutarate from substrate hydroxylation results in inactivated P4H, which can be rescued by ascorbate (25–27). Details of the mechanism by which P4H catalyzes hydroxylation have been proposed based on related α-ketoglutarate-dependent dioxygenases (28–30). In the initial steps of catalysis, decarboxylation of α-ketoglutarate produces an iron (IV)-oxo species. This highly reactive species abstracts the pro*R* hydrogen from C-4 of a proline residue in the substrate (31). A hydroxyl group is transferred to the radical intermediate to form the Hyp product.

P4H does not hydroxylate all proline residues. Free proline amino acids are not hydroxylated by P4H (32). Nor is polyproline hydroxylated, though it does bind to the enzyme and is a competitive inhibitor of enzymatic activity (33). Hydroxylation occurs only on proline residues in an Xaa–Pro–Gly sequence within a polypeptide. The strength of substrate binding increases with the length of the polypeptide but is obviated by triple-helical structure (34).

Computational, structural, and spectral analyses of Pro–Gly sequences in peptides and proteins have shown that adoption of a β-turn conformation is energetically favorable (5,35–37). Other conformation preferences for the substrates of prolyl 4-hydroxylase are less clear. Because proline is a secondary amine and prolyl peptide bonds are tertiary amides, the *cis* isomer of prolyl peptide bonds occurs much more frequently than in peptide bonds between non-prolyl residues (38). The conformation of the prolyl peptide bond is correlated with another conformational feature of proline—its ring pucker (39,40). The pyrrolidine ring of proline primarily adopts two puckered conformations: C^γ-*endo* and C^γ-*exo* (Figure 2).[3] The *trans/cis* ratio and ring pucker are both influenced by substituents on the pyrrolidine ring that evoke stereoelectronic effects (42).

In this work, we create variations in *trans/cis* ratio and preferred ring pucker by using proline analogs with subtle substitutions at the 4-position of the pyrrolidine ring (Figure 2). We then demonstrate that the ability of P4H to bind to a proline analog and catalyze its oxidation

---

[2]The abundance of Hyp in animal proteins is <4%, a value calculated from the abundance of collagen amongst animal proteins (⅓) and the prevalence of Hyp within the Xaa–Yaa–Gly sequence of collagen (<38% × ⅓) (2). The abundance of the "common" amino acids is given in ref. 3.

[3]The pyrrolidine ring of proline actually prefers two distinct twist, rather than envelope, conformations (41). As C^γ experiences a large out-of-plane displacement in these twisted rings, we refer to pyrrolidine ring conformations simply as "C^γ-*exo*" and "C^γ-*endo*".

correlates with the *trans*/*cis* ratio and preferred ring pucker. The results provide new insight into how this essential enzyme recognizes its substrate.

Experimental Procedures

Materials

Boc-FlpOH and Boc-flpOH were from OmegaChem (Lévis, Québec). Boc-protected amino acids were converted to their Fmoc derivatives via standard methods and used without further purification (43). Fluorenylmethoxycarbonyl (Fmoc)-mini-PEG-3™ (Fmoc-11-amino-3,6,9-trioxaundecanoic acid) was from Peptides International (Louisville, KY). Fmoc-ThpOH was from Advanced ChemTech (Louisville, KY). All other Fmoc-protected amino acids were from Novabiochem (La Jolla, CA). $[1^{-14}C]\alpha$-Ketoglutarate was from American Radiolabeled Chemicals (St. Louis, MO). All other chemicals were of reagent grade or better, and were used without further purification.

Synthesis of Boc-D,L-MtpOH

Boc-D,L-MtpOH was prepared by the route shown in Scheme 1, which is less costly and more convenient than those described previously (44,45). Briefly, carbamate **1** was prepared as in ref. [46], and then used in a manner similar to that in ref. [47]. Specifically, a solution of carbamate **1** (2.0 g, 10.91 mmol) and TMEDA (2.1 mL, 14.18 mmol, 1.3 equiv) in dry ether (50 mL) was cooled to −78 °C, and *s*-BuLi (10.1 mL, 14.18 mmol, 1.3 equiv, 1.4 M solution in cyclohexane) was added dropwise. The resulting solution was stirred for 2 h at −78 °C and then transferred *via* a canula to a solution of distilled DMF (6.3 mL, 81.83 mmol, 7.5 equiv) in dry diethyl ether (30 mL) that had been cooled to −78 °C. The solution was warmed slowly to room temperature, and then quenched with 10 mL saturated $NH_4Cl(aq)$. The ether layer was washed with distilled water (2×20 mL) and dried over $Na_2SO_4(s)$. After filtration and concentration, the oil was taken up in 10 mL of dry MeOH, and this solution was cooled to 0 °C. $NaBH_4$ (2.1 g, 54.56 mmol, 5.0 equiv) was added slowly to the solution, which was then stirred at 0 °C for 15 min. The reaction mixture was warmed to room temperature, and 10 mL of saturated $NH_4Cl(aq)$ was added slowly, followed by 30 mL of CH_2Cl_2. The aqueous layer was extracted with CH_2Cl_2 (3×30 mL). The organic extracts were combined, dried over $Na_2SO_4(s)$, and filtered. The solvent was removed under reduced pressure, and the residue was purified by chromatography on silica gel (3:2 hexanes/diethyl ether) to furnish $3\text{-}CH_2OH$ (**2**) (609 mg, 26%, $R_f = 0.36$ with 1:1 hexanes/diethyl ether), $1\text{-}CH_2OH$ (**3**) (638 mg, 27%, $R_f = 0.51$), and starting material **1** (190 mg, 10%, $R_f = 0.71$).

Following the procedure in refs. [44] and [47], $3\text{-}CH_2OH$ (**2**) (600 mg, 2.813 mmol) was dissolved in a solution of CH_2Cl_2 (14 mL), TEMPO (27 mg), saturated $NaHCO_3(aq)$ (11 mL), KBr (54 mg), and Bu_4NCl (67 mg). This solution was cooled to 0 °C, and a solution of NaOCl (14 mmol), saturated $NaHCO_3(aq)$ (6 mL), and brine (12 mL) was added dropwise over 45 min. The reaction mixture was stirred for an additional 1 h, and then warmed to room temperature. The aqueous layer was separated, and the organic layer was washed with 50% w/v $NaHCO_3(aq)$ (3×65 mL). The aqueous layers were combined, and washed with CH_2Cl_2 (2×25 mL), acidified with dilute HCl solution until the pH was <3, and then extracted with ethyl acetate (5×200 mL). The combined organic extracts were dried over $Na_2SO_4(s)$, and the solvent was removed to furnish Boc-D,L-MtpOH (524 mg, 82%) as off-white solid of sufficient purity (44,45,47).

Instrumentation

Measurements of UV and visible absorbance were made with a Cary model 3 spectrophotometer (Varian, Palo Alto, CA). Peptide synthesis was conducted with a Pioneer (PerCeptive Biosystems) or Symphony (Protein Technologies) automated synthesizer at the

University of Wisconsin Biotechnology Center. Preparative high-performance liquid chromatography (HPLC) was performed with a system from Waters (Milford, MA) equipped with two 510 pumps and a 486 tunable absorbance detector. Analytical HPLC was performed with a Waters system equipped with two 515 pumps, a 717 plus autosampler, and a 996 photodiode array detector. Fast protein liquid chromatography (FPLC) was performed with an ÄKTA system from Amersham Pharmacia (Piscataway, NJ). Matrix-assisted laser desorption/ ionization time-of-flight (MALDI–TOF) mass spectrometry was performed with a Perkin–Elmer (Wellesley, MA) Voyager MALDI–TOF mass spectrometer at the University of Wisconsin–Madison Biophysics Instrumentation Facility. Scintillation counting was performed with a Wallac 1450 MicroBeta TriLux liquid scintillation counter from Perkin–Elmer (Wellesley, MA).

Production and Purification of P4H

P4H was produced and purified by using procedures reported previously (18).

Synthesis of Peptides

Peptides were synthesized on a solid support (PEG-PS, Applied Biosystems) by standard Fmoc-protection methods using HATU activation. To increase the water-solubility of the Pro-, Flp-, flp-, Kep-, and Thp-containing peptides, a short PEG chain was added to their N-terminus. The PEG was added by coupling Fmoc-mini-PEG-3™ (Peptides International, Louisville, KY) to the N-terminus of the peptide while on solid support. The N-terminus remained protected with the Fmoc while the peptides were cleaved from the solid support with 8 mL of 95:2.5:2.5 trifluoroacetic acid (TFA)/triisopropylsilane/water, and then washed with CH_2Cl_2 and dried under vacuum. The dried peptide was heated at reflux with $SOCl_2$ (15-fold molar excess) in ethanol for 2 h. The solvent was removed by rotary evaporation under reduced pressure. The N-terminal Fmoc was then removed by stirring the peptide in 20% v/v piperidine in DMF for 20 min. The peptides were purified by preparatory HPLC with a gradient (10–30% v/v) of acetonitrile in water containing TFA (0.1% v/v) to yield PEG-Gly–Tyr–Yaa–GlyOEt. MALDI MS m/z: $[M + Na]^+$ Yaa = Pro (14% yield; calcd 632.3, found 632.6), Flp (6% yield; calcd 650.3; found 650.5), flp (72% yield; calcd 650.3; found 650.6), Kep (1.8% yield; calcd 646.3, found 646.5), Thp (8% yield; calcd 650.3; found 650.7).

Cbz-Gly–Tyr–Mtp–GlyOEt was synthesized by standard Fmoc-protection methods on solid support. The cleavage from solid support and esterification were performed as described for the PEGylated peptides. Purification was done by preparatory HPLC with a gradient (20–40% v/v) of acetonitrile in water. The synthesis was done with racemic Fmoc-D,L-Mtp, and the diastereomeric tetrapepetides were not separated. Cbz-Gly–Tyr–Mtp–GlyOEt was analyzed by MALDI–MS m/z: $[M + Na]^+$ (calcd 589.2, found 589.5).

Peptide concentrations were determined by absorbance measurement in 6 M guanidine hydrochloride at pH 6.5 using $\varepsilon = 1450$ $M^{-1}cm^{-1}$ at 276 nm (48).

HPLC-based Assay of Enzymatic Activity

An HPLC-based assay described previously (18) was used to monitor product formation by P4H. Assays were performed for 5 min at 30 °C in 100 μL of 50 mM Tris–HCl buffer, pH 7.8, containing bovine serum albumin (1 mg/mL), catalase (100 μg/mL), dithiothreitol (100 μM), ascorbate (2 mM), $FeSO_4$ (50 μM), P4H (90 nM), and α-ketoglutarate (500 μM). The tetrapeptide substrate (stock solution in ethanol) was added to initiate the reaction. The reactions were quenched by boiling for 60 s. All assays were performed in triplicate. A reversed-phase analytical Alltima HP C18 AQ column (4.6 × 250 mm) from Alltech (Deerfield, IL) was used to separate peptides by elution with aqueous acetonitrile (12–30 % v/v in 20 min) containing TFA (0.1% v/v) at 1.0 mL/min. Product formation was quantified by the substrate:

product ratio, as determined by integration of the $A_{214\,nm}$ with the Millennium32 software from Waters (Millford, MA).

[^{14}C]CO$_2$-Release Assay for Enzymatic Activity

An alternative means to assess P4H activity is to monitor the release of CO_2, which is a product of catalysis (Figure 1). Procedures for monitoring the release of [^{14}C]CO$_2$ from [1-^{14}C]α-ketoglutarate were as described elsewhere (23,49). Concentrations were the same as above, except for that of P4H (395 nM). All reactions were performed in duplicate and corrected for the rate of decarboxylation in the absence of the peptide substrate.

Reduction and Conversion of Kep

For analysis, the ketone in PEG-Gly–Tyr–Kep–GlyOEt was either reduced to the alcohol with sodium borohydride (10 equiv) for 30 min at room temperature or converted to the oxime via reaction with hydroxylamine (10 equiv) in 250 mM sodium phosphate buffer, pH 5.0, for 1 h at 100 °C.

Chemical Oxidation of Thp

A mixture of PEG-Gly–Tyr–Thp(O)–GlyOEt and PEG-Gly–Tyr–thp(O)–GlyOEt was produced by chemical oxidation of the Thp-containing peptide with either 3-chloroperoxybenzoic acid (MCPBA) (1 equiv) in chloroform for 2.5 h at room temperature or sodium periodate (1.1 equiv) in aqueous methanol (75%) for 30 min at 50 °C (50). A peptide containing Thp(O,O) was produced by reaction of the Thp-containing peptide with MCPBA (10 equiv) in chloroform for 5 h at room temperature.

Results

Design of Peptide Substrates for P4H

Previously, we reported on an HPLC-based assay for P4H activity using the peptide substrate dansyl-Gly–Phe–Pro–GlyOEt (18). This peptide is not especially soluble, and is thus not useful for assays at high concentration. To increase its solubility, the dansyl moiety was replaced with a short PEG segment. In addition, Phe was replaced by Tyr to aid in the determination of peptide concentration. PEG-Gly–Tyr–Pro–GlyOEt is a substrate for P4H with $k_{cat} = 360$ min^{-1}, $K_M = 0.58$ mM, and $k_{cat}/K_M = 1.0 \times 10^4$ M^{-1}s^{-1} (Table 1, kFigure 3). This $_{cat}/K_M$ value is 3-fold greater than that for dansyl-Gly–Phe–Pro–GlyOEt (18).

Flp does not Inhibit P4H

No product formation was detected when Flp was used as a substrate for P4H (data not shown). It is not surprising that P4H cannot turn over Flp because P4H abstracts the pro$R$ hydrogen from C-4 of a proline residue, and that hydrogen is replaced with fluorine in Flp. Likewise, Flp does not inhibit the P4H-catalyzed conversion of Pro to Hyp. Under standard P4H reaction conditions as described in the experimental procedures with PEG-Gly–Tyr–Pro–GlyOEt at 0.06 mM, which is an order of magnitude below its K_M value, PEG-Gly–Tyr–Flp–GlyOEt had no measurable effect on hydroxylation of the Pro-containing peptide (Figure 4).

flp is a Substrate for P4H

Unlike Flp, flp has a hydrogen in the 4R position of the pyrrolidine ring, and PEG-Gly–Tyr–flp–GlyOEt was determined to be a substrate for P4H (Figures 3 and 5). The product was identified as 4-ketoproline (Kep) by MALDI–MS (m/z 624.4, calc 624.3), and coeluted with a standard during HPLC (data not shown). Kep was characterized further by reduction of its ketone to a hydroxyl group with sodium borohydride (MALDI–MS m/z 626.6, calc 626.3) and reaction of its ketone with hydroxylamine to form an oxime (MALDI–MS m/z 639.5, calc

639.3) (Figure 5). Kep can form by hydroxylation of flp to produce a fluorohydrin, followed by the elimination of a fluoride ion. From triplicate P4H reactions under standard conditions with varying concentrations of PEG-Gly–Tyr–flp–GlyOEt, the value of k_{cat}/K_M was determined to be $(2.7 \pm 0.5) \times 10^3$ $M^{-1}s^{-1}$. This value is 27% that of the Pro-containing peptide, which has a k_{cat}/K_M value of $(10 \pm 0.6) \times 10^3$ $M^{-1}s^{-1}$ (Table 1, Figure 3).

Kep does not Inhibit P4H

Kep, the product of the P4H-catalyzed reaction of flp, was not found to be a substrate for P4H (data not shown). Like Flp, Kep did not even inhibit the P4H-catalyzed conversion of Pro to Hyp (Figure 4).

Thp is a Substrate for P4H

Thp has a sulfur atom bearing no hydrogen atoms at the 4-position of the thiazolidine ring. Nonetheless, PEG-Gly–Tyr–Thp–GlyOEt was found to be a substrate for P4H (Figure 6). P4H added a single oxygen atom to Thp to form a sulfoxide (Thp(O)) in the peptide product (MALDI–MS m/z 666.6, calc 666.3 $[M + Na]^+$). Thp(O) was also formed, along with its thp (O), in the Thp-containing peptide by chemical oxidation using MCPBA or sodium periodate. Oxidation by sodium periodate yielded two products with the same mass according to HPLC and MALDI–MS. Kanai and coworkers reported that this nonenzymatic reaction with a thioprolylpyrrolidine derivative substrate produces an 85:15 mixture of the 4R and 4S diastereomers (50). HPLC analysis of the sodium periodate reaction compared to the P4H-catalyzed formation of the sulfoxide showed that P4H produces the 4R diastereomer exclusively. Chemical oxidation by MCPBA yielded the sulfoxide diastereomers, as well as the sulfone (Thp(O,O); MALDI–MS m/z 682.4, calc 682.3 $[M + Na]^+$), which was not formed by P4H. From triplicate P4H reactions under standard conditions with varying concentrations of PEG-Gly–Tyr–Thp–GlyOEt, the k_{cat}/K_M value was determined to be $(1.2 \pm 0.3) \times 10^3$ $M^{-1}s^{-1}$, which is 12% that of the Pro-containing peptide (Table 1, Figure 3).

P4H Decarboxylates $[1\text{-}^{14}C]\alpha$-Ketoglutarate when Pro, flp or Thp is a Substrate

The HPLC-based assay described above identified flp- and Thp-containing peptides as novel substrates of P4H. These proline analogs, along with the Pro-containing peptide, were also tested in an assay for P4H activity that measures the release of $[^{14}C]CO_2$ from $[1\text{-}^{14}C]\alpha$-ketoglutarate. The rate of decarboxylation in the absence of the peptide substrate was subtracted from each measurement. Substrate concentrations for assays with the Pro-, flp-, and Thp-containing peptides were 58, 160, and 640 μM, which were 10% of the K_M values determined in the HPLC-based assay. Under these conditions the rate of CO_2 released in the presence of the Pro-containing peptide was 1.9 ± 0.7 μM/min (Table 2). The rate with flp in the peptide substrate was 0.5 ± 0.1 μM/min, which is 26% that of Pro; the rate with Thp was 0.1 ± 0.1 μM/min, 6% that of Pro. These rates follow closely the trend observed with the HPLC-based assay.

Mtp does not Inhibit P4H

Mtp, the bicyclic proline analog, was not found to be a substrate for P4H. No product was detected by either HPLC or mass spectrometry (data not shown). Like Flp and Kep, Mtp did not inhibit the P4H-catalyzed conversion of Pro to Hyp (Figure 4).

Discussion

P4H catalyzes an extremely difficult chemical reaction—the hydroxylation of an unactivated methylene group to form a secondary alcohol. The putative mechanism involves the oxidative decarboxylation of α-ketoglutarate, which promotes the formation of a highly reactive iron

(IV)-oxo species from molecular oxygen (28–30). This iron(IV)-oxo species then abstracts the pro*R* hydrogen from C-4 of a proline residue, replacing it with a hydroxyl group to form Hyp (31).

In previous work, proline analogs with substituents at C-3 and C-5 have been used to probe catalysis by P4H. Peptides containing a racemic mixture of 3-fluoroprolines in the Yaa position were found to be substrates for the enzyme (51). Peptides containing the proline analogs 3-exomethyleneproline (51), 5-oxaproline (52), and 3,4-dehydroproline (53–55) inhibited P4H activity. In our work, we have focused instead on C-4, which is the carbon that undergoes a change in covalency during the reaction catalyzed by P4H.[4]

Requirements of Nonnatural Proline Analogs for Turnover by P4H

P4H can elicit the homolytic cleavage of a C–H bond but not a C–F bond. The change from Pro to Flp is conservative from the perspective of sterics, as hydrogen and fluorine have comparable van der Waals radii ($r_H = 1.20$ Å; $r_F = 1.35$ Å (56)). A C–F bond ($\Delta H° = 116$ kcal/mol) is, however, much stronger than a C–H bond ($\Delta H° = 98$ kcal/mol). Accordingly, we were not surprised to learn that P4H cannot turn over Flp. This finding contrasts with reports by others in the 1960's that relied on less direct assays (57,58). We did, however, expect P4H to bind to Flp as it does to Pro. Yet, no inhibition of P4H activity by Flp was detectable (Table 1).

Unlike Flp, flp is a substrate for P4H. The stability of a carbon radical with an α-fluoro substituent is $\Delta H = 0.7$ kcal/mol greater than that of an unsubstituted carbon radical, according to homolytic bond dissociation enthalpies of 2-fluoropropane and propane calculated at 25 °C (59). Hence, the hydroxylation of flp should be somewhat faster than that of Pro. Of course, other factors contribute to the rate of an enzymatic reaction, and the actual values of k_{cat} are 360 and 250 min^{-1} for Pro and flp, respectively (Table 1).

The product of the turnover of flp by P4H is Kep (Figure 5). This product has notable utility for future studies of P4H in biological systems. The turnover of flp introduces a functional group—a ketone—with orthogonal reactivity into a protein. This group could serve as a handle for a proteomic analyses of P4H substrates (60), as flp can be incorporated into proteins by biosynthesis (61–65). Furthermore, the turnover of flp not only produces Kep, but also releases fluoride ion, whose detection could provide the basis for a direct, continuous assay of P4H activity.

The sulfide in the Thp-containing peptide is oxidized to a sulfoxide by P4H (Table 1; Figure 6). Sulfides can be oxidized by other dioxygenases, such as thymine hydroxylase (66), 4-hydroxyphenylpyruvate dioxygenase (67), and cysteine dioxygenase (68). Although the chemical oxidation of Thp produces both sulfoxide diastereomers (50), turnover by P4H produces only the 4*R* sulfoxide, which has the same relative stereochemistry as the natural product, Hyp. α-Ketoglutarate is decarboxylated when Thp, flp, or Pro is the substrate in a reaction with P4H (Table 2). The relative rates of the decarboxylation reactions (Thp < flp < Pro) is similar to that for Hyp production (Table 1). These data are consistent with Thp, flp, and Pro being turned over by the same mechanism.

Role of Proline Conformation in Substrate Binding by P4H

Proline is the only proteinogenic amino acid whose *trans* peptide bond isomer is favored only slightly over the *cis* isomer (38). In other peptide bonds, the *trans* conformation is favored greatly. Proline is also the only proteinogenic amino acid to contain a saturated ring. The five-

---

[4]The diastereomers of (2*S*)-4-methylproline have been reported to be neither substrates nor inhibitors of human P4H (51).

membered pyrrolidine ring of proline primarily adopts two conformations, C$^\gamma$-*endo* or C$^\gamma$-*exo* (Figure 2).[3] The pucker of its pyrrolidine ring and the isomerization of its peptide bond are correlated attributes of proline (39,40). Electronegative atoms such as fluorine ($\chi_F = 4.0$ (56); *cf.*: $\chi_H = 2.1$) alter the ring pucker via the *gauche* effect. A C$^\gamma$-*exo* pucker allows for an $n\rightarrow\pi^*$ interaction between the oxygen of the Xaa–Pro peptide bond and the carbon of the Pro–Gly peptide bond. In turn, this $n\rightarrow\pi^*$ interaction stabilizes a *trans* peptide bond. The absence of a significant $n\rightarrow\pi^*$ interaction in the C$^\gamma$-*endo* pucker favors a *cis* peptide bond (39,40).

The proline analogs used in this study differ in their predominant ring pucker (Figure 2). Hyp and Flp adopt a C$^\gamma$-*exo* pucker and have a high *trans*/*cis* ratio, whereas flp and Pro adopt a C$^\gamma$-*endo* pucker and have a low *trans*/*cis* ratio (40,69). The ring puckers of Kep and Thp have not been examined directly. Nonetheless, the *trans*/*cis* ratio of Kep is higher than that of Pro (70), and the *trans*/*cis* ratio of Thp is lower than that of Pro (71). We find that Pro, flp and Thp are substrates for P4H, and that Hyp, Flp, and Kep are neither substrates nor inhibitors of the enzyme. We therefore propose that proline analogs that favor the C$^\gamma$-*endo* pucker and have a low *trans*/*cis* ratio bind to the active site of P4H, and those that favor a C$^\gamma$-*exo* or other pucker and have a high *trans*/*cis* ratio do not.

To test our proposal, we determined the ability of P4H to recognize Mtp (Figure 2). In essence, this analog has *two* C-4 carbons and thus always displays both ring puckers (72). Mtp has a *trans*/*cis* ratio that is between that of Pro and flp (44). We find that P4H does not hydroxylate either C-4 carbon of Mtp, and that Mtp does not inhibit P4H activity. These results refine our proposal by suggesting a proline residue with C$^\gamma$-*exo* pucker does not bind to the active site of the enzyme.

Our data suggest a means by which P4H diminishes product inhibition, which is often detrimental to enzyme function (73,74). The stereoelectronic consequences of catalysis by P4H convert the Pro substrate into a Hyp product, which has a greater preference for a C$^\gamma$-*exo* ring pucker and *trans* peptide bond. These changes discourage P4H from binding previously hydroxylated collagen strands. A similar mechanism to avert product inhibition is employed by oligosaccharyl transferase, which catalyzes the formation of a *cis* amide bond during the *N*-glycosylation of asparagine residues. Isomerization to the *trans* conformations takes place after product release and prevents the product from binding again to the enzyme (75).

A summarial model for substrate recognition by P4H is shown in Figure 7. This model is based on the data herein, as well as known structures of Pro and Hyp. Previously, we used X-ray diffraction analysis to determine the three-dimensional structures of crystalline AcProOMe and AcHypOMe (76). In these structures, AcProOMe has a *cis* peptide bond and C$^\gamma$-*endo* ring pucker, and AcHypOMe has a *trans* peptide bond and C$^\gamma$-*exo* ring pucker. In the model, the iron(IV)-oxo species is proximal to the pro*R* hydrogen on C-4 of Pro, which is the single atom on the pyrrolidine ring that is farthest from the main chain of the peptide substrate. Thus, the hydrogen atom to be abstracted reaches most deeply into the enzymic active site. Hydroxylation then promotes a conformational change in the product that the P4H active site is unable to accommodate.

Conclusions

We have discovered two novel substrates for P4H: flp and Thp. These analogs demonstrate for the first time that perturbations can be made at the 4-position of a proline substrate with retention of high P4H activity. Other proline analogs investigated, Flp, Kep and Mtp, are not recognized by P4H. A comparison of the conformational preferences of these five proline analogs, along with Pro and Hyp, shows that proline analogs that prefer conformations similar to Pro—the substrate—are accepted by P4H, whereas analogs that are similar to Hyp—the

product—are not. Therefore, the P4H-catalyzed formation of Hyp promotes conformational changes that limit product inhibition. Moreover, each analog that binds to the active site of P4H is also a substrate, indicating that the enzyme discriminates at the level of substrate binding rather than substrate turnover. The highly reactive iron(IV)-oxo species that forms in the active site of P4H is perhaps the most powerful oxidizing agent in biology (30), and must therefore be sequestered deeply within its enzymic active site. Hence, P4H has an imperative for forming a snug complex with its substrate, and appears to do so.

Structures of prolines and its analogs studied herein, along with their predominant ring pucker. [3] Each amino acid was incorporated into a tetrapeptide and examined as a substrate or inhibitor of P4H.
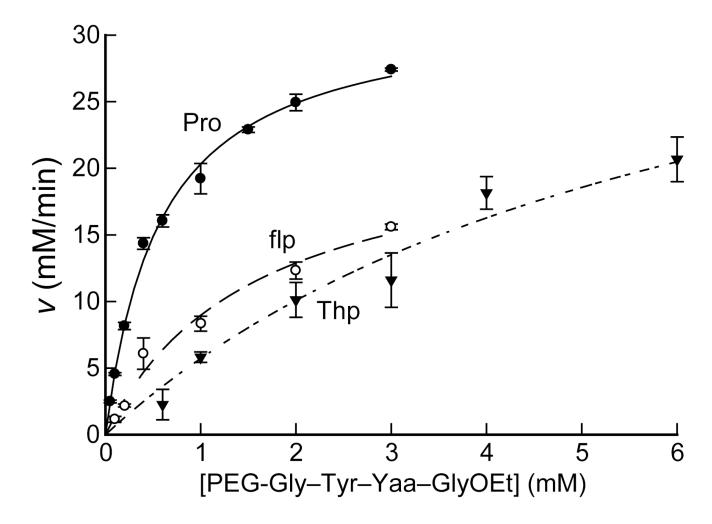

Figure 3.
Comparison of PEG-Gly–Tyr–Yaa–GlyOEt peptides, where Yaa = Pro (●), flp (○), or Thp
(▼;), as substrates of P4H. Plot shows the rate of product formation at varying substrate
concentrations. Reactions were performed as described in the Experimental Methods section.
Reactions were initiated by the addition of tetrapeptide substrate (0.05–3 mM), and run at 30
°C for 5 min. Product formation was analyzed by HPLC. Individual points are the average (±
SE) of three independent reactions. Data were fitted to the Michaelis–Menten equation to obtain
kinetic parameters.

Figure 4.
Peptides containing Flp, Kep, or Mtp do not inhibit Hyp formation from Pro by P4H. Graph shows the hydroxyproline formed from proline in the presence of no proline analog, Kep, Flp, or Mtp. The reaction with no proline analog was designated as 100%. Reactions contained 0.6 mM PEG-Gly–Tyr–Yaa–GlyOEt, where Yaa = Kep, Flp or Mtp, and 0.06 mM PEG-Gly–Tyr–Pro–GlyOEt. Individual points are the average (± SE) of three independent reactions.

Hyp	Neither[b]	–	–	–
Kep	Neither	–	–	–
Mtp	Neither	–	–	–

[a]Reaction components and conditions were as described in the text. Values represent the mean ($\pm$ SE) of three replicates.

[b]Data from ref. [37].

Table 2

Comparison of $[^{14}C]CO_2$ release from $[1-^{14}C]$ α-ketoglutarate in P4H assays with PEG-Gly–Tyr–Yaa–GlyOEt as the substrate[a]

Yaa	v (μM/min)	% of Pro
Pro	1.9 ± 0.7	100
flp	0.5 ± 0.1	26
Thp	0.1 ± 0.1	6

[a]Reactions were run in duplicate. The rate of decarboxylation in the absence of the peptide substrate was subtracted from each measurement. Components and conditions were as described in the text. Substrate concentrations were 58, 160, and 640μM, for Pro, flp, and Thp, respectively, which are 10% of each K_M value determined in the HPLC-based assay.
